#### **Dropout**

Dropout [1] is a technique for regularizing neural networks by randomly setting some output activations to zero during the forward pass. In this exercise you will implement a dropout layer and modify your fully-connected network to optionally use dropout.

y test: (1000,)
```

## **Dropout forward pass**

In the file libs/layers.py, implement the forward pass for dropout. Since dropout behaves differently during training and testing, make sure to implement the operation for both modes.

Once you have done so, run the cell below to test your implementation.

```
np.random.seed(231)
x = np.random.randn(500, 500) + 10
for p in [0.25, 0.4, 0.7]:
  out, _ = dropout_forward(x, {'mode': 'train', 'p': p})
  out test, = dropout forward(x, {'mode': 'test', 'p': p})
  print('Running tests with p = ', p)
  print('Mean of input: ', x.mean())
  print('Mean of train-time output: ', out.mean())
 print('Mean of test-time output: ', out_test.mean())
  print('Fraction of train-time output set to zero: ', (out ==
0).mean())
  print('Fraction of test-time output set to zero: ', (out test ==
0).mean())
  print()
Running tests with p = 0.25
Mean of input: 10.000207878477502
Mean of train-time output: 10.006234670544599
Mean of test-time output: 10.000207878477502
Fraction of train-time output set to zero: 0.749832
Fraction of test-time output set to zero: 0.0
Running tests with p = 0.4
Mean of input: 10.000207878477502
Mean of train-time output: 10.035153558044966
Mean of test-time output: 10.000207878477502
Fraction of train-time output set to zero: 0.598632
Fraction of test-time output set to zero: 0.0
Running tests with p = 0.7
Mean of input: 10.000207878477502
Mean of train-time output: 9.987811912159426
Mean of test-time output: 10.000207878477502
Fraction of train-time output set to zero: 0.30074
```

# **Dropout backward pass**

In the file libs/layers.py, implement the backward pass for dropout. After doing so, run the following cell to numerically gradient-check your implementation.

```
np.random.seed(231)
x = np.random.randn(10, 10) + 10
dout = np.random.randn(*x.shape)

dropout_param = {'mode': 'train', 'p': 0.2, 'seed': 123}
out, cache = dropout_forward(x, dropout_param)
dx = dropout_backward(dout, cache)
dx_num = eval_numerical_gradient_array(lambda xx: dropout_forward(xx, dropout_param)[0], x, dout)

# Error should be around e-10 or less
print('dx relative error: ', rel_error(dx, dx_num))
dx relative error: 0.6666666666771829
```

### **Fully-connected nets with Dropout**

In the file libs/classifiers/fc\_net.py, modify your implementation to use dropout. Specifically, if the constructor of the network receives a value that is not 1 for the dropout parameter, then the net should add a dropout layer immediately after every ReLU nonlinearity. After doing so, run the following to numerically gradient-check your implementation.

```
f = lambda : model.loss(X, y)[0]
    grad num = eval numerical gradient(f, model.params[name],
verbose=False, h=1e-5)
    print('%s relative error: %.2e' % (name, rel error(grad num,
grads[name])))
  print()
Running check with dropout = 1
Initial loss: 2.3004790897684924
W1 relative error: 1.48e-07
W2 relative error: 2.21e-05
W3 relative error: 3.53e-07
b1 relative error: 5.38e-09
b2 relative error: 2.09e-09
b3 relative error: 5.80e-11
Running check with dropout = 0.75
Initial loss: 2.302371489704412
W1 relative error: 2.80e-01
W2 relative error: 1.43e-01
W3 relative error: 2.60e-08
b1 relative error: 2.80e-01
b2 relative error: 1.43e-01
b3 relative error: 1.70e-10
Running check with dropout = 0.5
Initial loss: 2.310136908722148
W1 relative error: 6.00e-01
W2 relative error: 3.33e-01
W3 relative error: 4.49e-08
b1 relative error: 6.00e-01
b2 relative error: 3.33e-01
b3 relative error: 9.51e-11
```

### **Regularization experiment**

As an experiment, we will train a pair of two-layer networks on 500 training examples: one will use no dropout, and one will use a keep probability of 0.25. We will then visualize the training and validation accuracies of the two networks over time.

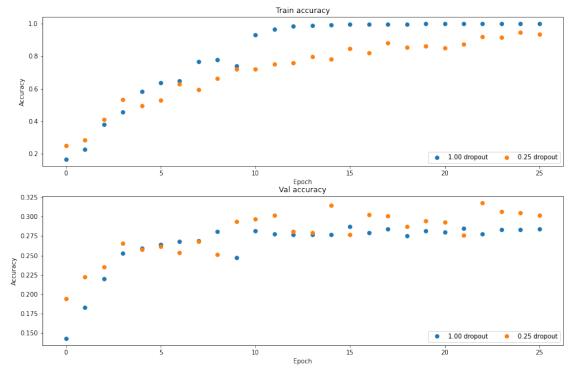

```
# Train two identical nets, one with dropout and one without
np.random.seed(231)
num_train = 500
small_data = {
   'X_train': data['X_train'][:num_train],
   'y_train': data['y_train'][:num_train],
   'X_val': data['X_val'],
   'y val': data['y val'],
```

```
}
solvers = {}
dropout choices = [1, 0.25]
for dropout in dropout choices:
  model = FullyConnectedNet([500], dropout=dropout)
  print(dropout)
  solver = Solver(model, small data,
                  num epochs=25, batch size=100,
                  update rule='sgd',
                  optim config={
                    'learning rate': 5e-4,
                  verbose=True, print every=100)
  solver.train()
  solvers[dropout] = solver
  print()
(Iteration 1 / 125) loss: 7.856644

# Question

Explain what you see in this experiment. What does it suggest about **dropout**?

Dropout appears to reduce overfitting to the training dataset since the model performs worse on the training data but performs better on the validation dataset.
